

Create an MLA formatted essay, with all sources cited, with each source with a working https link. In the essay state how investigators could use Wolfram technology, and a giant artificial brain, and human participants if necessary, to test individual parts of the Gateway Process, time travel, afterlife preview, punishing the dead, testing afterlife accountability, and all other parts of the Gateway Process. Wolfram technology and Wolfram Physics could and should especially, in the essay, test the Holographic Universe hypothesis of the Gateway Process, as time travel and afterlife preview both stem from that. In summary, use Wolfram technology to test the experiments and predictions in the essays below, and the Holographic Universe hypothesis. Please both synchronize and cite the following essays, in the order they were created, for this very essay:

18 September 2026

From the Gateway Hypothesis to a Computational Experimental Program: Wolfram Physics, Artificial Intelligence, and Tests of Time, Consciousness, and Postmortem Accountability

Introduction

The 1983 *Analysis and Assessment of Gateway Process*, prepared by Lieutenant Colonel Wayne M. McDonnell for the U.S. Army Operational Group and subsequently released through the CIA, represents one of the most unusual documents in the history of government-associated consciousness research. The report attempted to construct a theoretical explanation for the Gateway Experience by combining meditation, auditory entrainment, altered states of consciousness, quantum mechanics, consciousness theory, and a holographic conception of reality. Importantly, however, the report was an assessment of a speculative program, not a modern experimental demonstration that its more extraordinary conclusions were correct (McDonnell).

A contemporary research program could therefore ask a more rigorous question: **Can the individual claims underlying the Gateway Process be separated, formalized computationally, simulated where possible, and experimentally tested where necessary?** This essay proposes that Wolfram Language, Wolfram Physics models, large-scale artificial intelligence or neuromorphic systems, and carefully controlled human experiments could form a common research platform for doing precisely that.

This proposal follows a three-stage intellectual progression established in three earlier essays by Alexander Ohnemus. The first, "Temporal Information, Postmortem Accountability, and the Search for an Empirical Afterlife," frames the general problem of reconstructing information about past events and investigating whether consciousness or accountability could persist beyond biological death. The second, "A Philosophical Prediction of Universal Posthumous Apotheosis: Insights from the Gateway Process and Related Models of

Consciousness,” develops a philosophical prediction concerning universal postmortem transformation. The third, “From Philosophical Prediction to Experimental Test: Engineering the Gateway Process as a Falsifiable Afterlife Hypothesis,” turns toward experimentalization. Read consecutively, these works move from **information and accountability**, to **philosophical prediction**, to **experimental falsifiability** (Ohnemus, “Temporal Information”; Ohnemus, “Philosophical Prediction”; Ohnemus, “Experimental Test”).

The next step is to construct an integrated computational and experimental architecture.

I. The Gateway Process as a Collection of Testable Claims

The Gateway report should not be treated as one indivisible proposition. It contains numerous individual claims that can be separated experimentally. Among them are claims concerning auditory entrainment, relaxation, resonance, altered consciousness, out-of-body experiences, remote information acquisition, perception of past and future events, nonordinary dimensions, consciousness independent of the ordinary body, and the relationship between consciousness and a purported universal hologram (McDonnell).

The report specifically describes Hemi-Sync and frequency-following response as mechanisms intended to produce unusual states of consciousness. It also describes a progression through increasingly advanced Gateway states and eventually discusses Focus 15 as involving travel into the past and Focus 21 as involving access to future-oriented or nonordinary information (McDonnell). These claims are substantially more specific than the generic statement that meditation can produce unusual subjective experiences.

Consequently, the experimental program should begin by separating **subjective effects** from **information-acquisition effects**.

A participant might genuinely experience an out-of-body state without actually obtaining information unavailable to the ordinary senses. Likewise, a person might experience a vivid perception of the past without actually retrieving historically accurate information. These possibilities must be distinguished experimentally.

Modern neuroscience provides an important control here. Research on out-of-body experiences has associated them with disruptions in multisensory integration and activity involving the temporoparietal junction. Such findings demonstrate that an out-of-body experience can be scientifically investigated without presupposing that a consciousness literally leaves the body (Blanke and Arzy). Thus, Gateway research should measure both the reality of the experience and the much stronger claim that the experience provides externally verifiable information.

II. Wolfram Physics as a Test of the Holographic Hypothesis

The most important theoretical component of the proposed program is the Gateway report's "holographic" conception of reality. McDonnell's report presents a model in which the universe functions as a gigantic holographic information structure and human consciousness potentially accesses information encoded within it (McDonnell).

Modern theoretical physics provides a substantially different and much more mathematically developed meaning of "holographic." Leonard Susskind's holographic proposal argued that gravitational physics can admit a description in which information associated with a volume is represented on a lower-dimensional boundary. Juan Maldacena's AdS/CFT correspondence subsequently supplied an important concrete example of holographic duality in theoretical physics (Susskind; Maldacena). These theories should not be conflated with the Gateway report's consciousness model. Nevertheless, they make the word "holographic" scientifically meaningful enough that the underlying information-theoretic question can be investigated without simply accepting the Gateway interpretation.

This is where Wolfram Physics becomes particularly interesting.

The Wolfram Physics Project models physical reality using evolving hypergraphs and causal graphs. Its technical materials describe causal graphs as representations of causal relationships among update events and multiway systems as representations of multiple possible evolutionary paths. The project also discusses branchial graphs and relationships between its formalism and ideas such as holography and ER=EPR (Wolfram Physics Project, "Time and Spacetime"; "Graph Types"; "Q&A").

This does **not** demonstrate that the universe is a hologram in the Gateway sense. It does, however, provide a computational environment in which hypotheses concerning information, causality, branching, and spacetime can be expressed with mathematical precision.

A proposed "Gateway-Wolfram" experiment would therefore begin by formalizing the Gateway hypothesis into explicit computational propositions:

1. Is information about a prior state mathematically recoverable from later states of a physical model?
2. Under what conditions does a causal graph preserve information about earlier events?
3. Can multiple branches of a multiway system contain distinguishable records of alternative histories?
4. Can an observer embedded inside the model infer information about states that are not presently accessible through its ordinary causal neighborhood?
5. Does a holographic or boundary representation contain enough information to reconstruct states in the corresponding bulk model?
6. Are there mathematical circumstances under which apparently separated histories share information through a common causal or branchial structure?

These questions can be tested without assuming that human consciousness can travel through time.

The distinction is crucial. **A computational demonstration that information about an earlier state is encoded in a later state would be evidence about information**

preservation, not proof of human time travel. Conversely, failure to recover the information under mathematically appropriate conditions would place limits on the hypothesis.

III. Wolfram Models and the Problem of Time Travel

The Gateway report's theory of time travel depends on its interpretation of the universe as an information-containing hologram. McDonnell argues that because past, present, and future are represented within the universal holographic structure, sufficiently altered consciousness might theoretically obtain information about different temporal regions (McDonnell).

A Wolfram-based experiment could translate this into a much more conservative proposition:

If a computational universe contains complete or partially preserved information about its earlier states, can an embedded computational observer reconstruct those states without being physically transported into them?

This question can be addressed using controlled simulations.

Researchers could create a Wolfram model with a known initial state, allow it to evolve, deliberately conceal selected portions of the history, and then give an artificial observer access only to later-state information. The system could then be asked to reconstruct the hidden earlier information. Statistical controls would establish how much of the reconstruction could occur by ordinary inference rather than genuine recovery of otherwise inaccessible information.

The experiment could become increasingly difficult. Researchers could hide random information, historical information, causal information, and eventually information deliberately constructed so that ordinary prediction becomes extremely difficult. If reconstruction remains possible, the mechanism should be identified mathematically. If it fails, the boundary conditions should likewise be documented.

Such an experiment would be a genuine test of **temporal information retrieval**, even though it would not constitute physical time travel.

IV. The Giant Artificial Brain

A second major component could be a large artificial-brain system. "Giant artificial brain" should be understood here as an engineering concept rather than as a claim that present technology can create an artificial human consciousness.

Modern neuromorphic research combines artificial neural systems, spiking neural networks, brain-computer interfaces, biological neural networks, and specialized hardware. Recent reviews describe increasingly sophisticated approaches to neural recording, stimulation, signal decoding, neuromorphic computation, and brain-inspired interfaces (Fares et al.).

Such a system could function as an experimental intermediary between human consciousness research and computational physics.

The artificial brain would have at least four functions.

First, it could model the Gateway participant's physiological and cognitive state. EEG, heart rate, respiration, autonomic signals, eye movements, and other measurements could be synchronized with the participant's reported subjective experience.

Second, it could analyze Wolfram-generated causal and multiway structures. Instead of asking a human researcher to inspect enormous graphs manually, the artificial system could search for patterns, correlations, and candidate mechanisms.

Third, it could serve as an independent information-retrieval agent. Human participants could attempt to obtain information under Gateway conditions while the artificial system independently attempted to infer the same information from the available computational representation.

Fourth, the system could operate as a hypothesis generator. It could search enormous spaces of mathematical models for relationships between altered-state variables and measurable information-retrieval performance.

Wolfram Language is particularly appropriate for such a role because its environment includes symbolic mathematics, graph computation, statistical analysis, machine learning, signal processing, time-series analysis, and parallel computation. Wolfram's computational infrastructure also supports cloud evaluation and programmatic computation (Wolfram Research, "Wolfram Language"; "Parallel Computing"; "Wolfram APIs").

The artificial brain would therefore not need to be conscious. Its scientific value could arise from being a highly capable **computational control and analysis system**.

V. Testing Individual Gateway Techniques

The entire Gateway Process could then be decomposed into experimentally measurable modules.

Hemi-Sync and Auditory Entrainment

The first experiment would test whether the auditory protocols reliably alter EEG activity, interhemispheric synchronization, autonomic physiology, subjective relaxation, attention, or other measurable variables.

Participants would be randomly assigned to authentic Gateway-style auditory stimulation, carefully matched auditory controls, and possibly silence or conventional relaxation controls. EEG and physiological data would be collected continuously.

The purpose would not be to prove or disprove the entire Gateway theory from one experiment. It would determine whether its first proposed mechanism produces the physiological changes claimed for it.

Resonance and Physiological Synchronization

The Gateway report attributes considerable significance to bodily resonance, including relationships among heartbeat, breathing, brain activity, and electromagnetic phenomena (McDonnell).

A modern experiment could synchronize ECG, respiration, EEG, accelerometry, blood pressure, and other measurements. Wolfram analysis could determine whether stable cross-frequency relationships emerge above what would be expected by chance.

If they do, the phenomenon could be characterized quantitatively. If they do not, the proposed mechanism would require revision.

Altered Consciousness

Participants could receive standardized psychological and phenomenological questionnaires before and after each experimental condition. Neuroimaging and electrophysiological measurements could be used where appropriate.

The central question would be whether the Gateway protocol reliably creates a reproducible state rather than merely producing individually variable experiences.

Out-of-Body Experiences

OBEs should be divided into two hypotheses:

H1: Gateway techniques increase the probability or intensity of subjective out-of-body experiences.

H2: During those experiences, participants acquire information that they could not obtain through ordinary sensory or inferential means.

H1 is primarily a neuroscience question. H2 is an information-acquisition question.

The distinction prevents a genuine neurological phenomenon from being mistakenly treated as evidence for an extraordinary interpretation.

Remote Viewing

Gateway-style remote-viewing claims could be tested using preregistered targets selected after the experimental protocol has been locked. Participants would describe perceived targets while blinded to their identities.

Automated scoring could compare their descriptions against target images or environments using independently specified metrics. Wolfram systems could calculate statistical significance, effect sizes, multiple-comparison corrections, and Bayesian model comparisons.

The most important requirement would be that the scoring method be established before the results are known.

VI. Testing Focus 15 and Temporal Information Retrieval

The Gateway report associates Focus 15 with access to the past and describes the universal hologram as containing traces of events throughout temporal evolution (McDonnell).

This is one of the clearest opportunities for an actual falsifiable experiment.

Researchers could construct historical targets unknown to participants but independently verifiable. Participants would enter the relevant Gateway state and attempt to report information about the hidden target.

The targets should include multiple categories:

- documented historical events;
- physical locations;
- randomly generated computer states;
- hidden images;
- historical objects;
- events with independently preserved records;
- and events for which the researchers themselves do not know the answer.

The final category is particularly important. It prevents experimenters from unintentionally communicating the answer through expectation or subtle cues.

The giant artificial brain could independently analyze the participant's descriptions against all candidate targets. Wolfram Language could calculate likelihood ratios and determine whether the participant's performance exceeds chance.

This would transform "travel into the past" from a metaphysical assertion into a measurable information-retrieval hypothesis.

VII. Focus 21 and the Future

The future presents an even more difficult problem because a future event cannot ordinarily be treated as an already-observed historical fact.

A rigorous experiment could therefore distinguish **prediction** from **precognition**.

Researchers could generate future targets using cryptographically secure random processes after participants have completed their predictions. Participants would enter the designated Gateway state and attempt to report the future target.

If the target is selected after the prediction, ordinary inference becomes considerably less plausible as an explanation.

Repeated trials would be necessary. A single spectacular result would not establish the hypothesis.

The Wolfram system could simulate alternative explanations, including statistical selection effects, optional stopping, target similarity, multiple comparisons, and post hoc interpretation.

A successful result would therefore need to survive a computational battery of null hypotheses.

VIII. Testing an “Afterlife Preview”

The phrase “afterlife preview” encompasses several different claims and should not be treated as a single experimental variable.

The weakest claim is that Gateway experiences can produce vivid experiences interpreted by participants as encounters with deceased persons or nonordinary environments.

The stronger claim is that participants receive independently verifiable information concerning deceased individuals that they could not ordinarily know.

The strongest claim is that consciousness itself can persist independently of the biological organism.

The experiments should proceed in this order.

First, characterize the subjective experience.

Second, test information accuracy.

Third, test whether information can be obtained under blinded conditions.

Only after those stages produce anomalous results would the question of postmortem consciousness become experimentally compelling.

IX. Testing Postmortem Accountability

The concept of “punishing the dead” requires particularly careful scientific and ethical reformulation.

There is currently no established scientific method for demonstrating that a deceased person remains conscious, much less for physically or psychologically imposing consequences upon such a consciousness. Therefore, an experiment should not begin by attempting to harm or punish deceased persons.

Instead, the scientifically testable hypothesis could be called **postmortem accountability**:

If a person's consciousness persists after biological death, can that consciousness obtain or respond to accurate information concerning its previous actions and their consequences?

This could be investigated through highly controlled communication experiments involving alleged postmortem information, blinded target material, independently verified facts, and preregistered scoring.

A particularly strong version would involve information deliberately created after the person's death but unknown to all living participants until a predetermined disclosure point. If an alleged postmortem communicator could repeatedly provide statistically significant information from that hidden dataset, the result would warrant further investigation.

Even then, the interpretation would require extreme caution.

A successful information result could potentially indicate an unknown information pathway, fraud, leakage, statistical anomaly, or another explanation before establishing survival of consciousness.

Thus, the scientific objective should be **testing postmortem information and accountability**, not inflicting punishment.

X. Testing the Gateway Holographic Universe Hypothesis Directly

The central experiment should ultimately return to the holographic hypothesis.

A computational laboratory could create several classes of universe models:

1. ordinary causal networks;
2. Wolfram hypergraph models;
3. multiway systems;
4. systems with explicitly encoded holographic boundary information;
5. systems with hidden temporal states;
6. systems containing simulated observers;
7. systems containing artificial neural observers.

Researchers would then ask whether an observer restricted to a lower-dimensional or later-state representation could reconstruct information that, according to the model, exists elsewhere in the complete computational structure.

This creates a hierarchy of increasingly strong tests.

Level One: Information is mathematically encoded.

Level Two: An algorithm can recover it.

Level Three: An artificial neural system can recover it.

Level Four: Human participants can recover it under blinded conditions.

Level Five: Human participants outperform sophisticated artificial systems.

Level Six: The information concerns real-world events rather than simulated data.

Level Seven: The information cannot be explained by ordinary causal access, inference, sensory leakage, or statistical artifact.

Only the highest levels would begin to challenge conventional assumptions about consciousness and information.

This framework is valuable because it prevents the Gateway hypothesis from being tested only through subjective experience.

XI. A Unified Experimental Architecture

The resulting research program could therefore have five interacting layers.

Layer 1: Wolfram Physics.

Construct formal models of spacetime, causal graphs, multiway evolution, branching, information preservation, and holographic representations.

Layer 2: Wolfram computation.

Perform statistical analysis, symbolic mathematics, simulations, graph analysis, machine learning, and large-scale hypothesis testing.

Layer 3: Artificial brain.

Use a large AI or neuromorphic architecture to model observers, analyze physiological signals, search computational spaces, and independently evaluate human reports.

Layer 4: Human Gateway participants.

Conduct preregistered experiments involving relaxation, auditory entrainment, altered consciousness, OBE reports, remote viewing, temporal information retrieval, and prospective target prediction.

Layer 5: External validation.

Use blinded targets, independent laboratories, preregistration, open data where ethically permissible, independent replication, and adversarial statistical analysis.

The architecture is therefore not “Wolfram proves Gateway.” Instead, it is a framework in which **Wolfram computation can determine exactly what the Gateway hypothesis predicts and whether those predictions occur.**

XII. What Would Count as a Discovery?

The program should define its standards of success in advance.

A reproducible physiological effect from Hemi-Sync would establish a physiological effect.

A reproducible altered state would establish a reproducible altered state.

A reproducible OBE would establish that the experience can be experimentally induced.

Statistically significant remote information acquisition would establish an anomalous information result requiring explanation.

Successful reconstruction of hidden historical information would establish a temporal-information anomaly.

Successful prediction of future randomly generated information would establish a prospective-information anomaly.

Reliable acquisition of postmortem information would constitute an even more significant anomaly.

None of these results, by themselves, would automatically establish the Gateway report's complete metaphysical interpretation.

The same principle applies to Wolfram Physics. A Wolfram model exhibiting holographic mathematical behavior would not automatically demonstrate that consciousness accesses a cosmic hologram. Rather, it could establish that certain aspects of holographic information processing emerge naturally from a computational model of spacetime.

That distinction is precisely what makes the research scientifically useful.

Conclusion

The three preceding Ohnemus essays can therefore be understood as stages of a developing research program. The first asks whether information about past events and postmortem accountability could become empirically accessible. The second proposes a philosophical model of universal posthumous transformation based partly upon interpretations of the Gateway Process. The third asks how such propositions might be converted into falsifiable experiments (Ohnemus, "Temporal Information"; "Philosophical Prediction"; "Experimental Test").

The next stage is computational experimentalization.

Wolfram Physics provides an especially promising mathematical environment for examining the information-theoretic foundations of the proposal because its formalism explicitly represents evolving states, causal relationships, multiway evolution, and possible branching structures. Its discussion of holographic principles provides a legitimate point of contact with contemporary theoretical physics, although it should not be confused with the much more speculative holographic-consciousness theory presented in the Gateway report (Wolfram Physics Project, "Q&A").

A giant artificial brain could complement this approach by serving as an experimental observer, computational model, signal analyst, and adversarial hypothesis tester. Human

participants could then provide the final experimental component by attempting the Gateway techniques under blinded, preregistered conditions.

The most ambitious goal would be to determine whether information concerning the past, future, or alleged postmortem states can be obtained in a manner that cannot be explained by ordinary perception, inference, information leakage, chance, or experimental artifacts. The Gateway report's extraordinary claims would thereby become progressively more precise and progressively more difficult to dismiss—or to accept—without evidence.

The ultimate scientific question is consequently not whether the Gateway Process *sounds* plausible, nor whether a declassified government report described it favorably. The question is whether its individual mechanisms make predictions that survive controlled experimentation.

If the holographic universe hypothesis is correct in the strong sense envisioned by Gateway, then a rigorous computational program should eventually reveal measurable consequences. If it is incorrect, the same program should expose where the predictions fail.

That is the value of combining Wolfram Physics, artificial intelligence, human consciousness research, and rigorous experimental design: speculation can become simulation; simulation can become prediction; prediction can become experiment; and experiment can determine which parts of the original hypothesis, if any, survive.

This version deliberately makes **holographic information retrieval the central bridge** between your three essays and the proposed Wolfram/AI experimental program, while keeping "time travel," afterlife preview, and postmortem accountability as hypotheses requiring evidence rather than established capabilities.

Chat GPT prompt: You did not add working https links like <https://lnkd.in/p/gZ294Hct> . Please add working https links like <https://lnkd.in/p/gZ294Hct> .

Yes. You want the **actual HTTPS URLs written out in the MLA Works Cited entries**, not merely clickable anchor text. I also understand that you want the LinkedIn/[lnkd.in](https://lnkd.in/p/gZ294Hct) links formatted in the same style as your example, e.g. <https://lnkd.in/p/gZ294Hct>.

For the three essays you supplied, I would format the entries like this:
